What is Scabies?

Scabies is an allergic reaction to the body fluids of the mite *Sarcoptes Scabiei*.

The mites burrow into the deeper layers of skin where they lay eggs. The mites live for 1-2 months.

Signs of Infection

Mites can burrow anywhere but are more common on hands, arms, and particularly between the fingers. Sometimes a few are found on the genitals or female breasts.

The body can become very itchy with widespread rash. Itching of the rash can be worse at night. There may be small, raised pimples and patches of crusty skin.

The sites of the rash may not be in the same place as the mites. Not everybody will have sensitivity to the mite, and so not everybody develops a rash.

How does it spread?

Through long periods of skin to skin contact – for example, sexual contact and holding hands.

Treatment

Treatment is relatively straightforward. A number of creams / lotions are available – ask your GP or local Pharmacist. Apply the cream following the instructions.

Itching may persist for two to three weeks after the successful treatment, but it can be treated with a soothing lotion like calamine. Following successful treatment the rash will gradually fade.

How will this affect me and my family?

Avoid long periods of skin to skin contact. Signs of scabies take several weeks to appear, it is easy for close contacts (household and sexual) to become infected before the disease is known. Therefore, anyone who is in close contact with someone with scabies should also be treated whether they are itching or not.

The affected person may return to work, school or nursery 24 hours after the treatment has been commenced.

No special steps need to be taken with used clothing and bed linen, a hot cycle in a washing machine is enough.
